

NASA TECH BRIEF

NASA Tech Briefs announce new technology derived from the U.S. space program. They are issued to encourage commercial application. Tech Briefs are available on a subscription basis from the Clearinghouse for Federal Scientific and Technical Information, Springfield, Virginia 22151. Requests for individual copies or questions relating to the Tech Brief program may be directed to the Technology Utilization Division, NASA, Code UT, Washington, D.C. 20546.

A Self-Tuning Filter

Circuit Diagram of Self-Tuning Filter

The problem:

Bandpass filters are commonly used in electronic systems to improve the signal-to-noise ratio. If the frequency of the input signal is variable, as it is from many types of vibrating transducers, a wideband filter is frequently used to avoid signal attenuation and phase shift at the frequency extremes, and the filtering is then not as effective in rejecting noise.

The solution:

A self-tuning filter that automatically adjusts its center frequency to track the signal frequency. This technique permits the use of a filter with a bandwidth considerably smaller than the range of input signal frequencies.

How its done:

A resistance-capacitance bandpass filter whose center frequency can be varied by means of a single resistive element is used. However, instead of an ordinary

resistor, a field effect transistor (FET) is used so that the voltage of the tuning element can be controlled. The control voltage is derived from a phase detector which compares the phase of the filter input and output. If the phase between the input and output is 180° , the filter is tuned to the input frequency. If the phase is less than 180° , a correcting voltage is applied to the FET to retune the filter until the phase is 180° , at which time the filter is again in tune. A circuit diagram of the self-tuning filter is shown in the figure.

A reference frequency is not required as in lock-in amplifier filters. Also, there is no change in phase as the signal frequency varies. A self-tuning filter that covers the range from 2 kHz to 20 kHz, while maintaining constant bandwidth and center frequency gain, has been built. It can be made to cover other decades of frequency by switching capacitors.
